

SU JOK TREATMENT OF PROSTATIC ADENOMA

L.D.Sipachova, physician, medical and sanitary unit of Glavtiumengeologia, M.A.Sipachov, fifth-year student of the Medical academy, E.M.Niguinski, chief-physician of medical and sanitary unit "Geolog"

During the last 18 months we treated and analysed 20 cases of first- and second-degree prostatic adenoma. The patients' age varied from 55 to 75 years old. All of them were registered with the urologist and had undergone traditional medication treatment (Omnik, Proskar). Before Su Jok treatment all the patients had had a US investigation of the small pelvis organs which confirmed their diagnosis.

Six Ki treatment on the UM-Coldness byol-meridian and byol-chakra was carried out.

Some of employed approaches to treating this pathology are presented in Figs. 1, 2, 3.

Though a positive effect was observed already after 5 to 6 procedures, in each case the whole treatment course was no less than 10 sessions in order to make the results stable. On completion of the course each patient had another US investigation of the small pelvis organs. Based on the investigation results, one can state that there was objective improvement in the whole group of treated patients.

Despite this success, in order to strengthen the clinical effect and prevent relapses all the patients underwent one more course of treatment from prostatic adenoma. It consisted of 6 to 10 procedures. We observed further improvement of both the patients' condition and US investigation results. On the whole, improvement was 65 to 75 percent.

During the past eight months only two of these patients applied for medical aid due to unpronounced disuric disorders.
